

## Fermat and Euler's Theorems

### **theorem**

Fermat's Theorem is often called Fermat's "little" Theorem to distinguish it from his more famous "Last" theorem.

The theorem says that for any prime number  $p$  and any integer  $1 < a < p$

$$a^p \bmod p = a$$

Two equivalent statements are

$$a^{p-1} \bmod p = 1$$

$$(a^p - a) \bmod p = 0$$

The second statement is what we use in analyzing the RSA method, and the third is used in the combinatorial proof of the theorem.

Examples:

$$2^3 \bmod 3 = 8 \bmod 3 = 2$$

$$2^5 \bmod 5 = 32 \bmod 5 = 2$$

$$3^5 \bmod 5 = 243 \bmod 5 = 3$$

Consider  $p = 7$

$$1^6 \bmod 7 = 1$$

$$2^6 \bmod 7 = 64 \bmod 7 = 1$$

$$3^6 \bmod 7 = 729 \bmod 7 = 1$$

$$4^6 = 4096 \bmod 7 = 1$$

$$5^6 = 15625 \bmod 7 = 1$$

$$6^6 = 46656 \bmod 7 = 1$$

Here is a table from Laws of Cryptography for  $p = 13$ , which computes such powers more efficiently (by computing mod  $p$  at each step).

<b>p</b>	<b>a</b>	$a^1$	$a^2$	$a^3$	$a^4$	$a^5$	$a^6$	$a^7$	$a^8$	$a^9$	$a^{10}$	$a^{11}$	$a^{12}$
13	2	<b>2</b>	<b>4</b>	<b>8</b>	<b>3</b>	<b>6</b>	<b>12</b>	<b>11</b>	<b>9</b>	<b>5</b>	<b>10</b>	<b>7</b>	<b>1</b>
13	3	<b>3</b>	<b>9</b>	<b>1</b>	3	9	1	3	9	1	3	9	1
13	4	<b>4</b>	<b>3</b>	<b>12</b>	<b>9</b>	<b>10</b>	<b>1</b>	4	3	12	9	10	1
13	5	<b>5</b>	<b>12</b>	<b>8</b>	<b>1</b>	5	12	8	1	5	12	8	1
13	6	<b>6</b>	<b>10</b>	<b>8</b>	<b>9</b>	<b>2</b>	<b>12</b>	<b>7</b>	<b>3</b>	<b>5</b>	<b>4</b>	<b>11</b>	<b>1</b>
13	7	<b>7</b>	<b>10</b>	<b>5</b>	<b>9</b>	<b>11</b>	<b>12</b>	<b>6</b>	<b>3</b>	<b>8</b>	<b>4</b>	<b>2</b>	<b>1</b>
13	8	<b>8</b>	<b>12</b>	<b>5</b>	<b>1</b>	8	12	5	1	8	12	5	1
13	9	<b>9</b>	<b>3</b>	<b>1</b>	9	3	1	9	3	1	9	3	1
13	10	<b>10</b>	<b>9</b>	<b>12</b>	<b>3</b>	<b>4</b>	<b>1</b>	10	9	12	3	4	1
13	11	<b>11</b>	<b>4</b>	<b>5</b>	<b>3</b>	<b>7</b>	<b>12</b>	<b>2</b>	<b>9</b>	<b>8</b>	<b>10</b>	<b>6</b>	<b>1</b>
13	12	<b>12</b>	<b>1</b>	12	1	12	1	12	1	12	1	12	1

**Table 1.4 Fermat's Theorem for  $p = 13$ .**

[www.cs.utsa.edu/~wagner/lawsbookcolor/laws.pdf](http://www.cs.utsa.edu/~wagner/lawsbookcolor/laws.pdf)

Let's do the calculation for  $a = 7, p = 13$ :

$$7^{**1} = 7$$

$$7^{**2} = 49 - 3(13) = 10$$

$$7^{**3} = 70 - 5(13) = 5$$

$$7^{**4} = 35 - 2(13) = 9$$

$$7^{**5} = 63 - 4(13) = 11$$

$$7^{**6} = 77 - 5(13) = 12$$

$$7^{**7} = 84 - 6(13) = 6$$

$$\begin{aligned}
7^{**8} &= 42 - 3(13) = 3 \\
7^{**9} &= 21 - 1(13) = 8 \\
7^{**10} &= 56 - 4(13) = 4 \\
7^{**11} &= 28 - 2(13) = 2 \\
7^{**12} &= 14 - 1(13) = 1
\end{aligned}$$

As the theorem says, we cycle around to  $7^{12} \bmod 13 = 1$ . The number 7 is called a *generator* because its powers generate all the values in the field  $Z_{13}$ .

2, 6 and 11 are also generators for  $Z_{13}$ .

Other values for  $a$  have shorter repeats (2, 3, 4 or 6 long). The lengths of such runs must be divisors of 12 so that they can cycle around after 12 rounds.

### proofs of Fermat's Theorem

Fermat didn't actually prove his theorem. Euler proved something more general, the theorem we introduce below, and Fermat is a specific case of that.

There is a beautiful combinatorial proof called the "necklace proof". Here is a write-up:

<http://scienceblogs.com/evolutionblog/2010/04/15/a-combinatorial-proof-of-ferma/>

### combinatorial proof

We construct a necklace of  $p$  beads, choosing from  $a$  different colors. We start by threading beads onto a linear piece of string.

Since we can choose any one of  $a$  colors,  $p$  times, there are  $a^p$  possible sequences.

However, we wish to exclude arrangements where all the beads have the same color. There are  $a$  of these and so the number of arrangements is  $a^p - a$ .

Now, join the ends of the string. As a cycle, each shifted sequence becomes indistinguishable from the others. There are  $p$  such cyclic shifts for each linear arrangement. For example, any cyclic permutation of  $ABCBAAC$  looks the same:

Therefore, the total number of arrangements is reduced by a factor of  $p$ .

$$n = \frac{a^p - a}{p}$$

The key observation is that  $n$ , the number of different arrangements, is clearly an integer. So we have that

$$a^p - a = np$$

If we take the modulus of both sides ( $\text{mod } p$ ) we have the result we seek.

$$(a^p - a) \text{ mod } p = 0$$

□

### proof by induction

This proof is just as simple. We claim that

$$a^p \bmod p = a$$

The base case is  $1^p \bmod p = 1$ , which is obviously true.

The binomial theorem gives this expansion for

$$(a + 1)^p = a^p + \binom{p}{1}a^{p-1} + \binom{p}{2}a^{p-2} + \cdots + \binom{p}{p-1}a + 1$$

All terms on the right-hand side except the first and last have  $p$  as a factor, so  $\bmod p$  each is just zero. We have

$$(a + 1)^p \bmod p = (a^p + 1) \bmod p$$

For the inductive step, we may assume that  $a^p \bmod p = a$ , so this becomes

$$(a + 1)^p \bmod p = (a + 1) \bmod p$$

which completes the proof.

□

### consequence

A consequence of this theorem is that the sequence  $a^1, a^2, a^3 \dots a^{p-1}$  repeats, so the sequence  $a^p, a^{p+1} \dots a^{2p-1}$  consists of exactly the same values.

As the source says:

**Because  $a$  to a power  $x \bmod p$  always starts repeating after the power reaches  $p - 1$ , one can reduce the power  $\bmod p - 1$  and still get the same answer.”**

Thus no matter how big the power  $x$  in

$$a^x \bmod p$$

then let

$$y = x \bmod (p - 1)$$

and so

$$a^x \bmod p = a^y \bmod p$$

For example, mod 13:

$$\begin{aligned} a^{29} \bmod 13 &= a^{29 \bmod 12} \bmod 13 \\ &= a^5 \bmod 13 \end{aligned}$$

Of course, it is possible that the sequence may repeat even more quickly, as we saw with the table above.

## Euler

Euler's totient function  $\phi(n)$  is defined like so:

$$\phi(n) = n \prod \left(1 - \frac{1}{p_i}\right)$$

where the  $p_i$  are the prime factors of  $n$ . In number theory,  $\phi$  gives the count of the positive integers up to a given integer  $n$  that are relatively prime to  $n$ , that are not divisors of  $n$ .

## theorem

Relevant to our study of cryptography, Euler's Theorem says that for an integer  $a < p$  (not equal to 1):

$$a^{\phi(n)} \bmod n = 1$$

If  $n$  is prime this reduces to

$$\phi(n) = n \prod \left(1 - \frac{1}{n}\right) = n\left(1 - \frac{1}{n}\right) = n - 1$$

and so

$$a^{n-1} \bmod n = 1$$

Fermat's Theorem is a special case of Euler's Theorem, when  $n$  is prime.

We skip the proof. See

[https://artofproblemsolving.com/wiki/index.php?title=Euler%27s\\_Totient\\_Theorem](https://artofproblemsolving.com/wiki/index.php?title=Euler%27s_Totient_Theorem)

### cryptography

Here we are particularly interested in the situation where  $n$  has two large prime factors  $p$  and  $q$  and then:

$$\phi(n) = pq \left(1 - \frac{1}{p}\right)\left(1 - \frac{1}{q}\right) = (p-1)(q-1)$$

Furthermore, we have defined encryption followed by decryption in public key cryptography as  $m^{ed} \bmod n = m$ . We would like to show that this follows as a consequence of our definitions.

From now on, we write  $\phi$  for  $\phi(n)$ . Recall that  $d$  is defined to be the multiplicative inverse of  $e \bmod \phi$ .

Write out what's given:

$$\phi = (p-1)(q-1)$$

$$m^\phi \bmod n = 1$$

$$ed \bmod \phi = 1$$

Our chained encryption/decryption is  $(m^e)^d \bmod n$  or:

$$m^{ed} \bmod n$$

My source says: "similar to Fermat's Theorem, arithmetic in the exponent is taken mod  $\phi$ ."

The idea is that since

$$m^\phi \bmod n = 1$$

if we are computing any *other* power of  $m$ , say  $ed$ , we need only compute to the power of  $ed \bmod \phi$ , because beyond that, the sequence just repeats.

We saw the repetition for Fermat's Theorem; it happens here as well, even though  $n$  is not prime. However, it is required that  $m$  be coprime to  $n$ .

As a counter-example, take  $n = 6 = 2 * 3$ . Then  $\phi = 2$ .

Now,  $5^2 = 25 = 1 \bmod 6$ .

But  $4^2 = 16 \bmod 6 = 4$ . Thus, 4 to *any* power mod 6 is 4!. The difference is that 4 is not coprime to 6, but 5 is.

For the big example, we have  $m$  to the power  $ed$  and then mod  $pq$ , and we reduce the power  $ed \bmod \phi$  since  $\phi = (p - 1)(q - 1)$ .

(Assuming  $m$  has no common divisors with  $n$ ):

$$\begin{aligned} m^{ed} \bmod n &= m^{ed} \bmod pq \\ &= m^{ed \bmod \phi} \bmod pq \end{aligned}$$

But of course  $ed \bmod \phi = 1$  so this is just  $m$ .

Furthermore,  $m^{ed} = m^{de}$ , hence the ability to encrypt first with the private key and then decrypt with the public one.
